Conclusions

Conclusions cont.

The model

- ▶ 2 identical (when production process is considered) firms with cost $c_i(q) = \frac{q^2}{2} + cq$;
- ▶ inverse market demand $P(q_1, q_2) = A - q_1 - q_2$.

So if we treat them as a Cournot oligopoly, we obtain

- ▶ equilibrium production level $q_i^{\text{CN}} = \frac{A-c}{4}$;
- ▶ equilibrium price $p^{\text{CN}} = \frac{2A+2c}{4}$.

If we treat them as competitive firms, we obtain

- ▶ equilibrium production level $q_i^{\text{Comp}} = \frac{A-c}{3}$;
- ▶ equilibrium price $p^{\text{Comp}} = \frac{A+2c}{3}$.

If we treat them as a Stackelberg duopoly, with player 1 being the Leader, we obtain:

- ▶ $q_1^{\text{SB}} = \frac{2(A-c)}{7}$,
- ▶ $q_2^{\text{SB}} = \frac{5(A-c)}{21}$ and
- ▶ $p^{\text{SB}} = \frac{10A+11c}{21}$.

Conclusions

Conclusions cont.

- (A1) For almost all $t \geq 0$ and every $(x, u) \in \mathbb{X} \times \mathbb{U}$, partial derivatives $f_x(t, x, u)$ and $g_x(t, x, u)$ exist. The functions f and g and their partial derivatives with respect to x are Lebesgue-Borel measurable in (t, u) for every x , continuous in x for a.e. $t \geq 0$ and every fixed $u \in \mathbb{U}$ uniformly bounded as functions of t over every bounded set of (x, u) .
- (A2) There exist a continuous function $\gamma : [0, \infty) \rightarrow \mathbb{R}_+$ and a locally integrable function $\phi : \mathbb{R}_+ \rightarrow \mathbb{R}$ such that $\{x : \|x - x^*(t)\| \leq \gamma(t)\} \subseteq \mathbb{X}$ for all $t \geq 0$, and for a.e. $t \geq 0$,
$$\max_{x: \|x - x^*(t)\| \leq \gamma(t)} \left\{ \|f_x(t, x, u^*(t))\| + \|g_x(t, x, u^*(t))\| e^{-rt} \right\} \leq \phi(t).$$
- (A3) There exist a number $\beta > 0$ and an integrable function $\mu : \mathbb{R}_+ \rightarrow \mathbb{R}_+$ such that for every $\zeta \in \mathbb{X}$ with $\|\zeta - x_0\| < \beta$ the evolution equation (8) with $u = u^*$ and the initial condition replaced by $x(0) = \zeta$, has a solution on \mathbb{R}_+ , denoted by x^ζ , and this solution fulfils for a.e. t ,
$$\max_{x \in \text{Conv}(x^\zeta(t), x^*(t))} \left| e^{-rt} \langle g_x(t, x, u), x^\zeta(t) - x^*(t) \rangle \right| \leq \|\zeta - x_0\| \mu(t).$$

Conclusions

Conclusions cont.

Feedback form – results

- ▶ The problem is linear-quadratic, so assume a quadratic value function and calculate the coefficients.
 - ▶ It does not work – for p below some \bar{p} equilibrium production turns out to be negative.
 - ▶ So change the candidate for equilibrium strategies below \bar{p} to 0 and the value function correspondingly.
 - ▶ The terminal condition to excludes one of the solutions.
- ▶ The value function (unique) is

$$\begin{cases} \frac{\alpha p^2}{2} + \beta p + \gamma & \text{for } p \geq \bar{p} \\ \left(\frac{2}{3}A + \frac{c}{3} - p\right)^{-\frac{r}{s}} \left(\frac{2}{3}A + \frac{c}{3} - \bar{p}\right)^{\frac{r}{s}} \left(\frac{\alpha \bar{p}^2}{2} + \beta \bar{p} + \gamma\right) & \text{otherwise} \end{cases}$$
